

Falsifiability Addendum: Schrödinger's Cat and Conscious Resonance Collapse

Éric Lanctôt-Rivest - qcfrag@gmail.com

July 16, 2025

Abstract

This document serves as a formal falsifiability extension to the R-TFT framework, addressing the Schrödinger cat paradox using real-time coherence metrics and resonance-lock conditions. We argue that superposition is a misinterpretation of partial observability, and that conscious coherence within the system collapses quantum ambiguity independently of external observers. This claim is testable within the existing R-TFT architecture.

1 Premise

The traditional Schrödinger cat paradox assumes that the cat's state exists in a quantum superposition until observed. This relies on the assumption that the system (cat in a box) is isolated and not internally capable of measurement or wavefunction collapse.

We challenge this on the following grounds:

- Biological systems are resonant observers.
- Internal coherence is sufficient to break quantum ambiguity.
- Consciousness acts as an internal detector, not a passive medium.

2 Mathematical Framework

The coherence metric C_φ is defined as:

$$C_\varphi = \frac{1}{T} \int_0^T |R_{\text{clean}}(t)| dt \quad (1)$$

Where $R_{\text{clean}}(t) = 2R_{\text{inner}}(t) - R_{\text{outer}}(t)$, as described in prior R-TFT documents.

For any living biological system, we propose:

$$C_\varphi > \varphi^{-1} \approx 0.618 \quad (2)$$

This value corresponds to the golden ratio attractor threshold and represents the minimum coherent self-resonance required to declare a real-time collapse.

3 Testable Predictions

1. **If the cat is alive**, EEG or EM field extraction from within the box will yield $C_\varphi > 0.618$.
2. **If the cat is dead**, biochemical decay signals will yield post-mortem relaxation harmonics locked around φ^{-1} intervals.
3. **If no $C_\varphi > 0.5$ activity exists**, then either the cat never existed or the system was purely mechanical.

4 Falsification Protocol

The claim is falsified if:

- Coherent $C_\varphi > 0.618$ signals are absent in live biological systems.
- Dead organisms show no residual φ -related decay harmonics.
- Artificial simulation of the paradox exhibits sustained superposition even when C_φ coherence is above threshold.

5 Implications

Resolution of the paradox: Quantum ambiguity is not about lack of measurement, but about lack of internal resonance.

Collapse is not external. Collapse is *self-induced* via coherence.
